Report on Cancer Statistics in Alberta

Lung Cancer

November 2009

Surveillance - Cancer Bureau
Health Promotion, Disease and Injury Prevention

Purpose of the Report

The Surveillance Department-Cancer Bureau; Health Promotion, Disease and Injury Prevention; Alberta Health Services is dedicated to Alberta Health Services' strategic plan of quality (responsive to communities and improving population health), access (supporting research commitments) and sustainability. Specifically, the Surveillance Department contributes to the common goal of reducing the burden of cancer by conducting cancer *surveillance* through the collection, integration, analysis and dissemination of cancer related information.

This report is designed to provide comprehensive and detailed information regarding lung cancer in Alberta. This document will help support health professionals, researchers and policy makers in the planning, monitoring and evaluation of cancer-related health programs. It will also be a useful education tool for the general public and media.

Navigating the Report

This document provides information on lung cancer statistics in Alberta. Details about other individual cancer types are available within separate documents. The words highlighted in *dark blue* are terms described in detail within the **Glossary**.

Data Clarifications

In this document, the term "cancer" refers to *invasive cancers* unless otherwise specified. It is important to note that this document contains both actual and estimated data; distinctions are made where applicable. The numbers published in this report should be considered provisional, as a few cases and deaths may be registered in subsequent years. The data in this report reflect the state of the Alberta Cancer Registry as of June 1, 2009.

For detailed descriptions about data sources and how they affect data presented in this report, please see the **Data Sources and Quality** section.

Summary

- Approximately **1 in 13** men and **1 in 15** women will develop invasive lung cancer within their lifetime.
- In 2006, **20,650** potential years of life were lost due to lung cancer.
- As of December 31, 2006, approximately **3,070** Albertans were alive who had previously been diagnosed with lung cancer.
- In 2006, there were **1,752** new cases of lung cancer in Alberta and **1,357** deaths due to the disease.
- If current trends continue, approximately **1,030** male and **1,070** female cases of lung cancer are expected to be diagnosed in 2011.
- The five-year relative survival for lung cancer in Alberta is approximately **13%** for those diagnosed between 2004 and 2006.

Probability of Developing and Dying from Lung Cancer

The **_probability of developing or dying of cancer_** measures the risk of an individual in a given age range developing or dying of cancer, and is conditional on the person being lung cancer-free prior to the beginning of that age range.

It is important to note that the probabilities of developing and dying of cancer represent all of Alberta's population on average and should be interpreted with caution at the individual level. In addition, someone diagnosed with cancer has a higher probability of developing another cancer in the future.[1]

Table 5-1: Probability of Developing Lung Cancer by Age and Sex, Alberta, 2006

Age Group	Males	Females
Lifetime Risk (all ages)	1 in 13	1 in 15
0 - 20	Less than 1 in 10,000	Less than 1 in 10,000
20 - 30	Less than 1 in 10,000	Less than 1 in 10,000
30 - 40	Less than 1 in 10,000	1 in 3,257
40 - 50	1 in 824	1 in 606
50 - 60	1 in 156	1 in 150
60 - 70	1 in 46	1 in 52
70 - 80	1 in 27	1 in 38
80+	1 in 22	1 in 42

Approximately 1 in 13 males and 1 in 15 females will develop invasive lung cancer in their lifetime (**Table 5-1**).

The probability of developing lung increases with age. The bottom eight rows of the table show the probability of developing lung cancer by the end of the age range for a lung cancer-free individual at the beginning of the age range. For instance, a lung cancer-free female at age 40 has a 1 in 606 chance of developing lung cancer by the time she is 50.

Table 5-2: Probability of Dying from Lung Cancer by Age and Sex, Alberta, 2006

Age Group	Males	Females
Lifetime Risk (all ages)	1 in 15	1 in 18
0 - 20	Less than 1 in 10,000	Less than 1 in 10,000
20 - 30	Less than 1 in 10,000	Less than 1 in 10,000
30 - 40	Less than 1 in 10,000	1 in 7,519
40 - 50	1 in 1,109	1 in 953
50 - 60	1 in 213	1 in 212
60 - 70	1 in 65	1 in 70
70 - 80	1 in 35	1 in 47
80+	1 in 23	1 in 41

The probability of dying from lung cancer varies by age and sex (**Table 5-2**). Approximately 1 in 18 females and 1 in 15 males will die of invasive lung cancer. The probability of dying from lung cancer increases with age. The bottom eight rows of the table show the probability of a cancer-free individual at the beginning of the age range dying from lung cancer by the end of the age range. For example, a cancer-free female at age 40 has a 1 in 953 chance of dying from lung cancer by the time she is 50.

Potential Years of Life Lost

One frequently used measure of premature death is *potential years of life lost (PYLL)*. PYLL due to cancer is an estimate of the number of years that people would have lived had they not died from cancer. PYLL was calculated by obtaining the number of deaths and the mean life expectancy of each age group. The results are a reflection of how many people died, their ages at death, and life expectancy. Life expectancy is calculated by determining the age to which an individual would have been expected to live had they not died from cancer. PYLL is one way to measure the impact, or burden, of a disease on a population.

Figure 5-1: Potential Years of Life Lost (PYLL) from Lung[*] Cancer Compared with Colorectal[*], Breast[†] and Prostate[‡], Alberta, 2006
[*] Male and Female
[†] Female only
[‡] Male only

In 2006, **20,650** potential years of life were lost due to lung cancer, which constitutes 24.3% of PYLL for all cancers (**Figure 5-1**).

Prevalence

The *prevalence* of a disease is defined as the number of people currently living with that disease. In this section of the report, the cancer prevalence presented describes the number of people alive as of December 31, 2006 who had ever been diagnosed with lung cancer.

Prevalence is a useful indicator of the impact of cancer on individuals, the healthcare system and the community as a whole. Although many cancer survivors lead healthy and productive lives, the experience can have a strong impact on the physical and emotional well-being of individuals and their families. The cancer experience can also result in the continued use of the healthcare system through rehabilitation or support services, as well as loss of work productivity that can affect the whole community.

As of December 31, 2006, approximately **3,070** Albertans were alive who had previously been diagnosed with lung cancer.

Lung Cancer Incidence and Mortality

Introduction

Incidence counts are the number of new cancer cases diagnosed during a specific time period in a specific population. In this section of the report, incidence counts refer to the number of new lung cancer diagnoses in Alberta in a calendar year. Incidence *rates* are the number of new cancer cases diagnosed per 100,000 population in a specific time period.

Mortality counts describe the number of deaths attributed to cancer during a specific period of time in a specific population. In this section of the report, mortality refers to the number of deaths due to lung cancer in Alberta in a calendar year, regardless of date of diagnosis. Mortality rates are the number of deaths per 100,000 population in a specific time period.

In order to compare cancer incidence or cancer mortality over time or between populations, *age-standardized incidence rates (ASIRs)* or *age-standardized mortality rates (ASMRs)* are presented. These are weighted averages of *age-specific rates* using a standard population. These rates are useful because they are adjusted for differences in age distributions in a population over time, which permit comparisons of cancer incidence or mortality between populations that differ in size, structure or time period. ASIRs and ASMRs give the overall incidence and mortality rates that would have occurred if the population of Alberta had been the same as the standard population. In this report the Canadian 1991 population is used as the standard population.

Three-year moving averages are used to smooth out year-to-year fluctuations so that the underlying trend may be more easily observed. They are calculated based on aggregating three years of data. Age-standardized incidence rates (ASIRs) and age-standardized mortality rates (ASMRs) are presented as three-year moving averages. This smoothing of trends is especially important when the number of cancer cases per year is relatively small, where year-to-year variability can be quite large.

Incidence and mortality can be affected by the implementation of public health prevention or screening strategies that either prevent disease or find cancer in its early *stages* when treatment is generally more successful, the development of cancer treatment programs that may impact chances of survival, and research innovations.

The following three figures show incidence and mortality trends in Alberta. Separate analyses for both incidence and mortality are shown in subsequent sections. Significant increases or decreases were detected using Joinpoint[2] and are described in the text accompanying each graph. JoinPoint models are based on yearly rates; hence there may be slight differences in the rates presented in the text (from JoinPoint model) and the graphs (where ASIRs and ASMRs are shown as three-year moving averages).

Figure 5-2: Age-Standardized Incidence Rates (ASIRs)[*†] and Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer, Both Sexes, Alberta, 1986-2006

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Lung cancer ASIRs have increased since 1986 (**Figure 5-2**). Between 1986 and 2006 lung cancer ASIRs increased 8% from 49.5 to 53.2 per 100,000. This corresponds to an annual increase in lung cancer rates of 0.4% between 1986 and 2006 assuming an equal increase in each year.

Mortality rates are lower than incidence rates. ASMRs have increased significantly since 1986 (**Figure 5-2**). Between 1986 and 2006 lung cancer ASMRs increased 9% from 39.7 to 43.1 per 100,000. This corresponds to an annual increase in lung cancer rates of 0.4% between 1986 and 2006.

Figure 5-3: Age-Standardized Incidence Rates (ASIRs)[*†] and Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer, Males, Alberta, 1986-2006

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Male lung cancer ASIRs have decreased significantly since 1986 (**Figure 5-3**). Between 1986 and 2006 lung cancer ASIRs decreased 19% from 75.6 to 61.0 per 100,000. If we assume the rate of decrease is the same in each year, this rate corresponds to an annual decrease in lung cancer rates of 1.1% between 1986 and 2006.

Male mortality rates are lower than male incidence rates. Male lung cancer ASMRs have not changed significantly between 1986 and 1988 (**Figure 5-3**). Male lung cancer ASMRs increased from 1986 to 1988 and remained unchanged until 1990. Between 1990 and 2006 male lung cancer ASMRs decreased 21% from 63.6 to 50.3 per 100,000. This corresponds to an annual reduction in lung cancer mortality rates of 1.3% between 1990 and 2006.

ASMRs fluctuated more than ASIRs in the 1980s and 1990s; however, in general, the trends for both incidence rates and mortality rates are decreasing.

Figure 5-4: Age-Standardized Incidence Rates (ASIRs) and Age-Standardized Mortality Rates (ASMRs) for Lung Cancer, Females, Alberta, 1986-2006

* Three-year moving average.
† Standardized to 1991 Canadian population.

Female lung cancer ASIRs have increased significantly since 1986 (**Figure 5-4**). Between 1986 and 2006 female lung cancer ASIRs increased 64% from 29.7 to 48.6 per 100,000. Assuming the rate of increase is similar in each year, this corresponds to an annual increase in lung cancer rates of 2.5% between 1986 and 2006 for females.

Female mortality rates are lower than incidence rates. Over the period 1986 to 1996, female lung cancer ASMRs increased 59% from 19.9 to 31.6, corresponding to an annual increase of 4.7% (**Figure 5-4**). Between 1996 and 2006 female lung cancer ASMRs increased 14% from 31.6 to 35.9 per 100,000. This corresponds to an annual increase in lung cancer rates of 1.3% between 1996 and 2006.

Lung Cancer Incidence

The following five figures (**Figures 5-5 to 5-9**) provide information on lung cancer incidence in Alberta. The number of new cancer cases in Alberta is affected not only by changes in the incidence rates, but also by the changes in the age structure and growth of the population. In order to compare trends over time, age-standardized incidence rates (ASIRs) are also provided.

Years 2006-2011 in **Figures 5-5** and **5-6** are shown as *projections*, which are estimates of new cancer cases and cancer rates that may occur in the future. The projected cancer numbers were calculated by applying the estimated five-year age-specific cancer incidence rates to the projected age-specific population figures (observed up to 2008 and estimated for 2009-2011) provided by Alberta Health and Wellness.[3] Caution should be exercised when comparing Canada[4] and Alberta rates due to minor differences between the Canadian Cancer Society and Alberta Cancer Registry classification of lung cancer.

The estimated cancer incidence rates were calculated by extrapolating the recent trends in observed five-year age-specific rates, which were modeled using log-linear regression.[5] For those age groups where there were few cancers for most of the years, the average rates for the most recent five years were used.

Figure 5-5: Actual and Projected Number of New Cases and Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer, Males, Alberta, 1986-2011

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

In 2006, 935 cases of male lung cancer were diagnosed in Alberta (**Figure 5-5**). ASIRs for lung cancer in Alberta were lower than ASIRs in Canada between 1987 and 2005.

If current trends continue, about 1030 cases of male lung cancer will be diagnosed in Alberta in 2011.

Figure 5-6: Actual and Projected Number of New Cases and Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer, Females, Alberta, 1986-2011

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

In 2006, 817 cases of female lung cancer were diagnosed in Alberta (**Figure 5-6**). This was about three times as many cases as were diagnosed in 1986. ASIRs for female lung cancer in Alberta were lower than ASIRs in Canada between 1987 and 2002; however, the rates for Canada and Alberta converge after 2003 with just a slight gap in 2005.

If current trends continue, about 1070 cases of female lung cancer will be diagnosed in Alberta in 2011.

Figure 5-7: Age-Specific Incidence Rates for Lung Cancer by Sex, Alberta, 2002-2006
Lung cancer rates remain low until about age 40 when they begin increasing in both males and women. At age 60, male rates continue increasing rapidly until age 80, while female rates increase more slowly until age 75 (**Figure 5-7**).

Figure 5-8: Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer, Ages <50, 50-64, 65-74, and 75+, Males, Alberta, 1986-2006

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Age-standardized lung cancer incidence rates in males differ across all four age groups (**Figure 5-8**). Fluctuations in the trend of ASIRs are visible for 65-74 and 75+ age groups.

Lung cancer incidence rates for males significantly declined over the period 1986 to 2006 for the age groups under 50, 50 to 64, and 65 to 74. Lung cancer incidence rates for males in the <50 age group declined by 44% from 4.1 to 2.3, an average annual decrease of 2.8%. In the males between 50 and 64 age group, lung cancer incidence rates declined by 37% from 152.7 to 96.9, an average annual decrease of 2.2%. In the males between 65 and 74 age group, lung cancer incidence rates declined by 18% from 407.2 to 333.9, an average annual decrease of 1.0%. The lung cancer incidence rates of those 75 and older did not significantly change over the same time period.

Figure 5-9: Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer, Ages <50, 50-64, 65-74, and 75+, Females, Alberta, 1986-2006

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Age-standardized lung cancer incidence rates for females differ across age groups (**Figure 5-9**).

The lung cancer incidence rates of females under age 50 did not significantly change over the period 1986 to 2006. Lung cancer incidence rates significantly increased over the period 1986 to 2006 for females in age groups 50 to 64, 65 to 74, and 75 and older. In the females 50 to 64 group, lung cancer incidence rates rose by 25% from 82.6 to 103.1, an average annual increase of 1.1%. In the females 65 to 74 group, lung cancer incidence rates rose by 79% from 149.5 to 267.4, an average annual increase of 2.9% assuming a similar rate of increase for each year. In females 75 and older, lung cancer incidence rates rose by 148% from 127.2 to 316.0, an average annual increase of 4.7%.

Lung Cancer Mortality

The following five figures (**Figures 5-10 to 5-14**) provide information on lung cancer mortality in Alberta. The number of deaths in Alberta is affected not only by changes in the mortality rates, but also by the changes in the age structure and growth of the population. In order to compare trends over time, age-standardized mortality rates (ASMRs) are also provided.

Years 2007-2011 in **Figures 5-10** and **5-11** are shown as *projections*, which are estimates of the number of cancer deaths and cancer mortality rates that may occur in the future. The projected numbers of cancer deaths were calculated by applying the estimated five-year age-specific cancer mortality rates to the projected age specific population figures (observed up to 2008 and estimated for 2009-2011) provided by Alberta Health and Wellness.[3] Caution should be exercised when comparing Canada[4] and Alberta rates due to minor differences between the Canadian Cancer Society and Alberta Cancer Registry classification of lung cancer.

The estimated cancer mortality rates were calculated by extrapolating the recent trends in observed five-year age-specific rates, which were modeled using log-linear regression.[5] For those age groups where there were few cancers deaths for most of the years, the average rates for the most recent five years were used.

Figure 5-10: Actual and Projected Number of Deaths and Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer, Males, Alberta, 1986-2011

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

In 2006, an estimated 726 males died of lung cancer in Alberta (**Figure 5-10**). ASMRs for male lung cancer in Alberta were lower than ASMRs in Canada between 1986 and 2004.

If current trends continue, about 850 males are expected to die from lung cancer in Alberta in 2011.

Figure 5-11: Actual and Projected Number of Deaths and Age-Standardized Mortality Rates (ASMRs)[*†]
**for Lung Cancer, Females, Alberta, 1986-2011**

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

In 2006, 631 females died of lung cancer in Alberta (**Figure 5-11**). ASMRs for female lung cancer in Alberta were lower than ASMRs in Canada between 1987 and 2004; however, the gap is closing. The ASMRs for Canada and Alberta converged in the years 1995, 2000, 2001, and 2003. Starting from 2004, the ASMRs for Alberta are projected to be lower than those of Canada.

If current trends continue, about 840 females are expected to die from lung cancer in Alberta in 2011.

Figure 5-12: Age-Specific Mortality Rates for Lung Cancer by Sex, Alberta, 2002-2006

Male and female lung cancer mortality rates differ by age (**Figure 5-12**). Age-specific mortality rates for lung cancer in both sexes increase rapidly after the age of 45. Female rates are similar to male rates until the age of 55 after which female mortality rates are lower compared to mortality rates in males.

Male mortality rates peaks at around age 80 and then decline, whereas female mortality rates peak at around age 75 and decline thereafter.

Figure 5-13: Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer, Ages <50, 50-64, 65-74, and 75+, Males, Alberta, 1986-2006

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Age-standardized lung cancer mortality rates in males vary over time and by age group (**Figure 5-13**).

Male mortality rates for lung cancer in the under 50, 50 to 64 and 65 to 74 age groups declined significantly between 1986 and 2006. Rates for those under 50 decreased by 42%, from 2.9 to 1.7 per 100,000, an average annual decrease of 2.7%. Rates for those aged 50 to 64 decreased by 34% from 116.2 to 76.2 per 100,000, an average annual decrease of 2.1%. Rates for those aged 65 to 74 decreased by 24% from 344.2 to 262.9 per 100,000, an average annual decrease of 1.3%. Lung cancer mortality rates for the remaining age group, those over 75, did not significantly change over the same period; however, there are a lot of fluctuations in the trend for this age group.

Figure 5-14: Age-Standardized Mortality Rates (ASMRs)[*†] **for Lung Cancer, Ages <50, 50-64, 65-74, and 75+, Females, Alberta, 1986-2006**

[*] Three-year moving average.
[†] Standardized to 1991 Canadian population.

Age-standardized lung cancer mortality rates for females vary over time and by age group (**Figure 5-14**).

Female mortality rates for lung cancer in the 50 to 64, 65 to 74 and 75 and over age groups rose significantly between 1986 and 2006. Rates for those aged 50 to 64 rose by 48% from 51.3 to 76.0 per 100,000 over the period 1986 through 1997, an average annual increase of 3.6%. For the period 1997 through 2006, the rates for this age group did not significantly change. Rates for those aged 65 to 74 rose by 81% from 113.5 to 205.3 per 100,000, an average annual increase of 3.0%. Rates for those over 75 rose by 156% from 111.1 to 284.1 per 100,000, an average annual increase of 4.8%. Lung cancer mortality rates for the remaining age group, those under 50, did not significantly change over the same period.

Lung Cancer Survival

Cancer survival ratios indicate the proportion of people who will be alive at a given time after they have been diagnosed with cancer. Survival is an important outcome measure and is used for evaluating the effectiveness of cancer control programs.

Survival depends on several factors including the cancer type (most importantly site, stage and morphology at diagnosis), sex, age at diagnosis, health status and available treatments for that cancer. While *relative survival ratios* give a general expectation of survival over the whole province, these ratios may not apply to individual cases. Individual survival outcomes depend on the stage of diagnosis, treatment and other individual circumstances.

Relative survival ratios are estimated by comparing the survival of cancer patients with that expected in the general population of Albertans of the same age, sex and in the same calendar year. Ratios are estimated by the *cohort method* (solid line) when complete follow-up data (e.g., at least five years of follow-up to estimate five-year rate) after diagnosis are available. For recently diagnosed cases, whose complete follow-up data are not available, the up-to-date estimates are computed using the *period method* (dashed line). Relative survival ratio is usually expressed as a percentage (%) and the closer the value is to 100%, the more similar the survival pattern is to the general population.
Figure 5-15: Relative Survival Trends for Lung Cancer, Both Sexes, Alberta, (1984-1986, 1994-1996 and 2004-2006)
—— (solid line): Ratios calculated by cohort method, where complete follow-up data are available
------ (dashed line): Ratios calculated by period method, where complete follow-up data are not available

There has been no improvement nor any changes in the relative survival ratios for individuals with lung cancer since 1984-1986 (**Figure 5-15**) and the five-year relative survival ratio remains stable for the recently diagnosed cases in 2004-2006. The five-year relative survival ratio of 13% indicates that, out of all individuals diagnosed with this cancer between 2004 and 2006, around 13% are as likely to be alive five years after diagnosis as members of the general Alberta population.
Figure 5-16: Relative Survival Trends for Lung Cancer, Males, Alberta, (1984-1986, 1994-1996 and 2004-2006)

—— (solid line): Ratios calculated by cohort method, where complete follow-up data are available
------ (dashed line): Ratios calculated by period method, where complete follow-up data are not available

The five-year relative survival ratio for males diagnosed with lung cancer has decreased by approximately 1% from 1984-1986 to 2004-2006 cohort years (**Figure 5-16**). The five-year relative survival ratio of 10% indicates that, out of males diagnosed with this cancer between 2004 and 2006, around 10% are as likely to be alive five years after diagnosis as males in the general Alberta population.
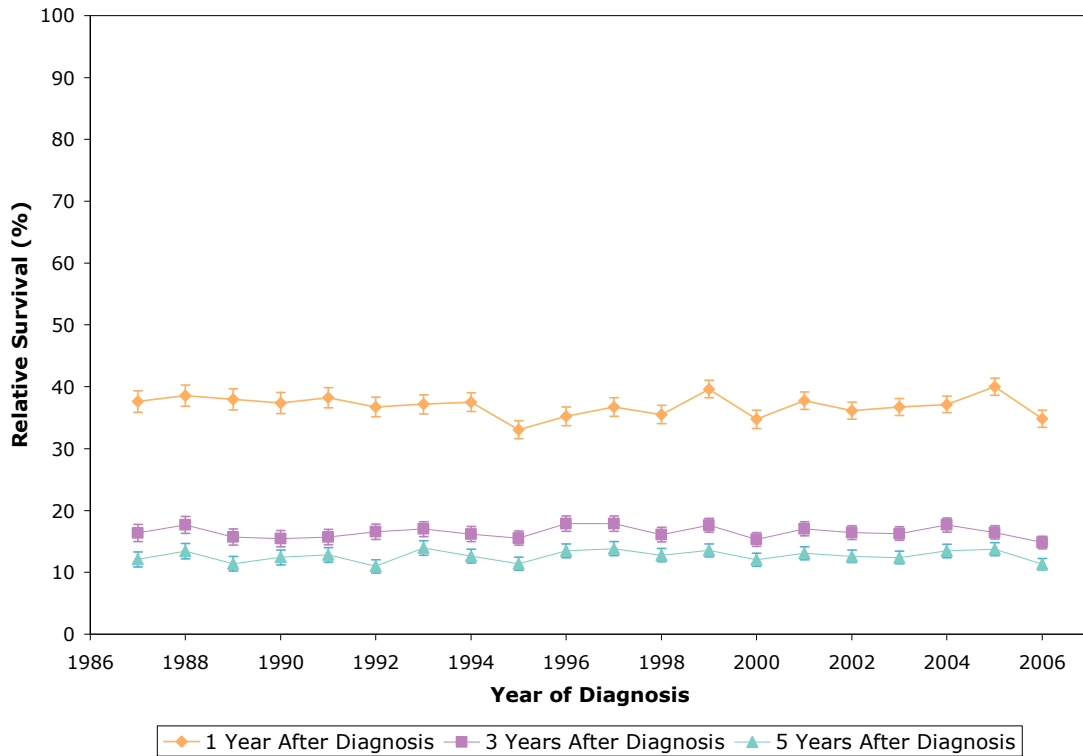

Figure 5-17: Relative Survival Trends for Lung Cancer, Females, Alberta, (1984-1986, 1994-1996 and 2004-2006)

—— (solid line): Ratios calculated by cohort method, where complete follow-up data are available
------ (dashed line): Ratios calculated by period method, where complete follow-up data are not available

There has been little improvement in the relative survival ratio of females with lung cancer since 1984-1986 (**Figure 5-17**) and this improvement in the five-year relative survival ratio for the recently diagnosed (2004-2006) cases is approximately 1%. The five-year relative survival ratio of 16% indicates that, out of females diagnosed with this cancer between 2004 and 2006, around 16% are as likely to be alive five years after diagnosis as females in the general Alberta population.

Figure 5-18: One-Year, Three-, and Five-Year Relative Survival Ratios for Lung Cancer, Both Sexes, Alberta, (1987-2006)

—— (solid line): Ratios calculated by cohort method, where complete follow-up data are available
------ (dashed line): Ratios calculated by period method, where complete follow-up data are not available

There have been no major improvements in the one-, three-, and five- year relative survival ratios for lung cancer (**Figure 5-18**).

Geographic Variation

The geographic variation section illustrates how the observed rates in each former regional health authority compare with the provincial average. These rates are three-year averages. The age standardized incidence and mortality rates for each former regional health authority are presented. Any observed differences in rates may be due to several factors such as regional differences in:

- risk factors such as smoking and obesity rates
- prevention efforts
- diagnostic activity
- access to cancer care.[6]

Figure 5-19: Former Regional Health Authorities in Alberta
Alberta was divided into nine Regional Health Authorities (**Figure 5-19**).

Figure 5-20: Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer by Former Alberta Regional Health Authority, Males, Alberta, 2004-2006[‡]
[*] Three-year average.
[†] Standardized to 1991 Canadian population.
[‡]Error bars represent 95% *confidence intervals*.

There is no evidence that age-standardized lung cancer incidence rates for males in former health regions are higher or lower than the provincial average (**Figure 5-20**).

Figure 5-21: Age-Standardized Incidence Rates (ASIRs)[*†] for Lung Cancer by Former Alberta Regional Health Authority, Females, Three-Year Average, Alberta, 2004-2006[‡]

[*] Three-year average.
[†] Standardized to 1991 Canadian population.
[‡]Error bars represent 95% *confidence intervals*.

There is no evidence that age-standardized lung cancer incidence rates for females in former health regions are higher or lower than the provincial average (**Figure 5-21**).

Figure 5-22: Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer by Former Alberta Regional Health Authority, Males, Alberta, 2004-2006[‡]

[*] Three-year average.
[†] Standardized to 1991 Canadian population.
[‡]Error bars represent 95% *confidence intervals*.

There is no evidence that age-standardized lung cancer mortality rates for males in former health regions are higher or lower than the provincial average (**Figure 5-22**).

Figure 5-23: Age-Standardized Mortality Rates (ASMRs)[*†] for Lung Cancer by Former Alberta Regional Health Authority, Females, Alberta, 2004-2006[‡]

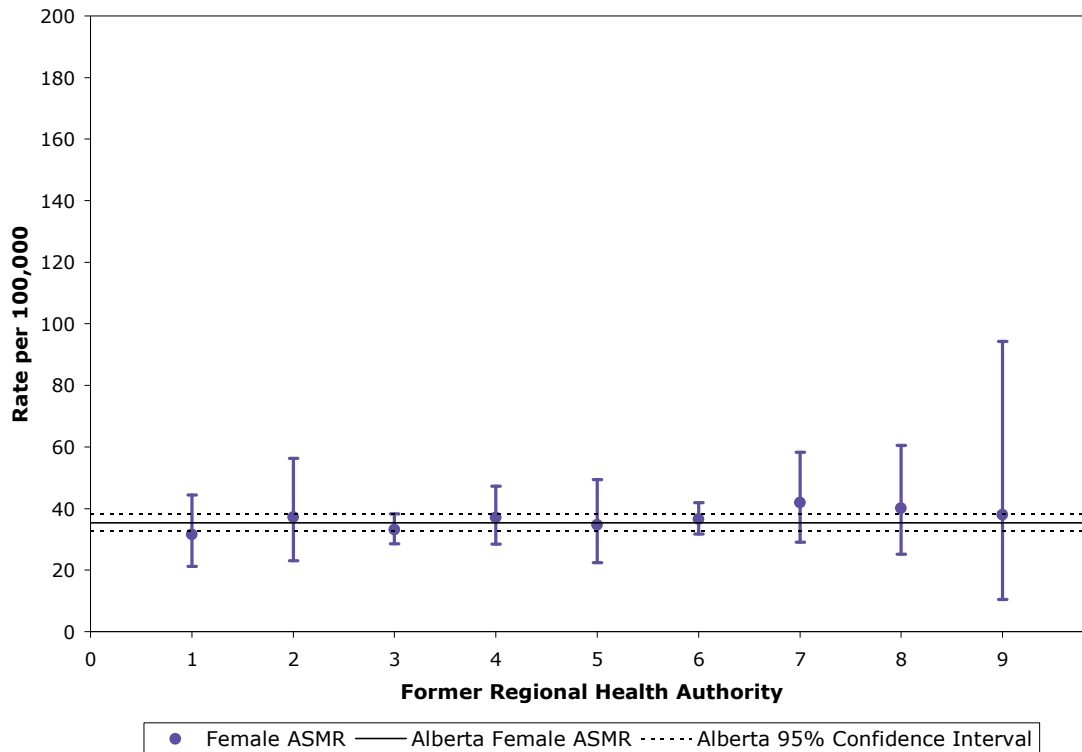

[*] Three-year average.
[†] Standardized to 1991 Canadian population.
[‡]Error bars represent 95% *confidence intervals*.

There is no evidence female age-standardized lung cancer mortality rates in former health regions are higher or lower than the provincial average (**Figure 5-23**).

Further Information

Data Sources and Quality

The data presented within this report are derived from the Alberta Cancer Registry (ACR). The ACR is responsible for recording and maintaining data on all new primary cancers, as well as all cancer deaths occurring within the province of Alberta, as mandated by the Regional Health Authorities (RHA) Act of Alberta.[7]

The quality of data collected by any registry is dependent on three factors: comparability, completeness and validity. Firstly, comparability is accomplished by applying standard practices regarding classification and coding of new cases and by using consistent definitions, such as the coding of multiple primaries. To achieve comparability, the ACR employs the International Classification for Oncology (ICD-O-2 for 1986-2000 data and ICD-O-3 for 2001 onwards) to classify all cancers by site and morphology. Cancer deaths are coded using the International Statistical Classification of Diseases and Related Health Problems (ICD-9 for 1986-2000 data and ICD-10 for 2001 onwards).

Secondly, completeness refers to the extent to which all the cancers in Alberta are accurately captured by the ACR. The ACR is notified of new cancers by doctors and laboratories throughout the province, who are mandated to report such information. Cancer-related deaths are recorded and validated by the ACR using registry and Alberta Vital Statistics information. Over the years, the ACR has achieved a completeness of over 95%.

Lastly, validity depends on the documentation available and the level of expertise in the abstracting, coding and recording of data within a registry. The ACR has numerous data edits to ensure all information is input as accurately as possible. For example, date of diagnosis of cancer must be after the date of birth. There are additional data quality reviews performed on ACR data by the Canadian Cancer Registry and the North American Association of Central Cancer Registries (NAACCR).

Confidentiality and security of personal information are protected by the RHA Act and the Health Information Act (HIA). The Alberta Cancer Registry maintains the trust of the public, the government, the data provider, and the general public by requiring rigorous confidentiality and security practices, in accordance with the RHA Act and HIA, to access the Registry database. Formal policies on information disclosure are available on request from the Alberta Cancer Registry.

By recording information on cancer cases and cancer-related deaths over the past few decades, the Alberta Cancer Registry has been able to compare cancer statistics in Alberta with other provinces and countries. The Registry also provides information to health care stakeholders throughout the province so that they can plan effective prevention, treatment and research programs.

For many years, the Alberta Cancer Registry has been certified by NAACCR and has achieved a Gold Standard for completeness of the data, timely reporting and other measures that judge data quality.

Glossary of Terms

Age-specific rates:
The number of new cancer cases or cancer deaths per 100,000 people per year within a given age group.

Age-standardized (incidence/mortality) rates:
A weighted average of age-specific rates using a standard population distribution. They reflect the overall rates that would be expected if the population of interest had an age structure identical to the standard population they used to compare cancer rates among populations or identify trends over time.

Benign:
A tumour that is not malignant (i.e. does not spread).

Carcinoma:
A tumour that begins in the skin or in tissues that line or cover body organs.

Confidence intervals:
An indication of the reliability of an estimate. A wide confidence interval indicates less precision and occurs when a population size is small.

Count:
Count refers to the number of cases (primaries) or deaths in a given time period. One patient may have multiple primaries.

Incidence count:
The frequency of new cancer cases during a period of time; often the number of new invasive cases diagnosed in a year.

Invasive cancer:
Cancer with the ability to spread beyond its point of origin.

Life table:
A life table estimates, for people at a certain age, what the probability is that they die before their next birthday. From this starting point, a number of statistics can be derived and thus also included in the table: a) the probability of surviving any particular year of age; b) remaining life expectancy for people at different ages; c) the proportion of the original birth cohort still alive. They are usually constructed separately for males and females because of their substantially different mortality rates.

Lymphatic system:
A system of vessels that carry lymph between lymph nodes located throughout the body.

Malignant:
Refers to a tumour that invades and destroys surrounding tissues, may spread elsewhere in the body, and is likely to recur after removal; a cancerous tumour.

Median Age:
The age at which half of the population is older and half is younger.[8]

Metastasis:
Refers to the spread of the original tumour to other parts of the body.

Mortality count:
The number of deaths due to cancer during a period of time.

Potential years of life lost (PYLL):
PYLL is the total number of years of life lost obtained by multiplying, for each age group, the number of deaths by the life expectancy of survivors. The indicator was calculated by obtaining the number of deaths and mean life expectancy for each age group.[4]

Prevalence:
The number of people alive at a specific point in time with cancer. Complete prevalence is the number of people alive today who have *ever* been diagnosed with cancer. In this document, we report complete prevalence.

Primary Site of Cancer:
The tissue or organ in which the cancer originates.[9]

Probability of developing/dying of cancer:
The risk of an individual in a given age range developing/dying of cancer in a given time period, and is conditional on the person being cancer-free prior to the beginning of that age range.

Prognosis:
A prediction about the outcome or likelihood of recovering from a given cancer.

Projection:
An estimate of cancer incidence or mortality in the future, based on recent historical trends.

Rate:
The number of cancer cases or deaths occurring in a specified time period.

Relative survival:
The survival of cancer patients relative to that of the general population, assuming cancer was the only cause of death. It is the ratio of observed survival in a group of cancer patients relative to the expected survival of a similar group of people in the general public, matched by age and sex in Alberta.

Stage of cancer:
Refers to the degree of cancer progression and the size of tumor at the time of diagnosis. If the cancer has spread, the stage describes how far it has spread from the original site to other parts of the body.[8]

Surveillance:
Cancer surveillance includes the collection of data, and the review, analysis and dissemination of findings on incidence (new cases), prevalence, morbidity, survival and mortality. Surveillance also serves to collect information on the knowledge, attitudes and behaviours of the public with respect to practices that prevent cancer, facilitate screening, extend survival and improve quality of life.[10]

Survival - Cohort method:
The cohort method provides survival estimates of cases having complete follow-up for the number of years of survival of interest. For example, cases diagnosed in 2001, for which vital status data are available to the end of year 2006, the cohort method may be used to obtain an estimate of five-year survival. The cohort survival represents the actual survival experience of individuals.

Survival - Period analysis:
The period method provides up-to-date survival estimate of recently diagnosed cases considering the survival experience of those cases within the most recent calendar period that allows for the estimation of a given period of survival. For example, to estimate the five year survival for cases diagnosed in 2004-2006, this method considers zero to one year survival experience for cases diagnosed in 2004-2006, one to two year survival experience for cases diagnosed in 2003-2005 who survived at least one year, and so on up to four to five year survival experience for cases diagnosed in 2000-2002 who survived at least four years.

Three-year moving average:
Three-year moving averages are used to smooth out year-to-year fluctuations in age-standardized rates so that the underlying trend may be more easily observed. They are calculated based on aggregating three years of data.

Tumour:
An abnormal mass of tissue that is not inflammatory, arises without obvious cause from cells of pre-existent tissue, and possesses no physiologic function.
