Prevention and Treatment of Acneiform Rash in Patients Treated with EGFR Inhibitor Therapies

Effective Date: November, 2020
Background

The epidermal growth factor receptor (EGFR) plays a central role in tumour growth and proliferation, and over-expression of EGFR is correlated with a poor prognosis, disease progression, and reduced sensitivity to chemotherapy.\(^1\) EGFR-targeted agents are used in several types of cancer, including lung, colorectal, breast, pancreatic, and head and neck. Classes of EGFR inhibitors include monoclonal antibodies (e.g. cetuximab, panitumumab, pertuzumub) and small molecular weight tyrosine kinase inhibitors (e.g. erlotinib, gefitinib, lapatinib, afatinib, osimertinib). These agents have been evaluated in phase II and III trials and are increasingly being incorporated into therapeutic plans for patients, both as front-line therapy, and after progression on standard chemotherapy.

EGFR inhibitors are generally well tolerated and are not associated with the moderate or severe systemic side effects of standard cancer therapies such as chemotherapy or radiation. However, because of the role of EGFR in skin biology they are associated with a variety of dermatologic reactions.\(^2\) The most commonly reported side effect is acneiform (papulopustular) rash; Table 1 lists the incidence rate for each EGFR inhibitor. Acneiform rash is typically localized to the face, scalp, upper chest and back. Although it is usually mild or moderate in severity, it can cause significant physical and psychosocial distress in patients, which may lead to decreased quality of life, and disruption or discontinuation of therapy.\(^3\), \(^4\) Thus, timely and appropriate interventions are essential.\(^5\)

Table 1. Incidence of acneiform eruption and skin rash

<table>
<thead>
<tr>
<th>EGF Inhibitor</th>
<th>Incidence of Acneiform Eruption and Skin Rash</th>
</tr>
</thead>
</table>
| Afatinib      | • Acneiform eruption: \(\sim\)90\%\(^6\)  
                 • Skin rash: \(\leq\)90\%\(^6\)  
                 • In LUX-Lung 3 and 8, incidence of Grade 3 cutaneous reactions ranged from 6.6\% to 16.2\%\(^7\) |
| Cetuximab    | • Acneiform eruption: 15-88\%\(^8\)  
                 • Skin rash: 28-44\%\(^8\)  
                 • Acneiform rash occurred in 76-88\% of patients; severe acneiform rash occurred in 1-18\% of patients\(^9\) |
| Erlotinib    | • Acneiform eruption: 4-5\%\(^10\)  
                 • Skin rash: 49-85\%\(^10\)  
                 o Grade 3: 5-13\%  
                 o Grade 4: <1\% |
| Gefitinib    | • Acneiform eruption: 6\%\(^11\)  
                 • Skin rash: 52\%,\(^11\) mainly mild or moderate\(^12\) |
| Lapatinib    | • Acneiform eruption: not reported\(^13\)  
                 • Skin rash: 28-44\% (combination therapy with capecitabine or letrozole)\(^13\), generally low grade\(^14\) |
| Osimertinib | • Acneiform eruption: not reported\(^15\)  
                 • Skin rash: 58\%,\(^15\) mainly mild\(^16\) |
| Panitumumab  | • Acneiform eruption:\(^17\)  
                 o 57\%; grades 3/4: 7\% (monotherapy)  
                 o 32\%; grades 3/4: 10\% (combination therapy with FOLFOX)  
                 • Skin rash:\(^17\) |
The onset of acneiform rash is most commonly observed during the first one to two weeks of treatment with an EGFR inhibitor, although the range of onset reported in the literature is between two days and six weeks. The rash typically progresses through four phases:

- Phase one (weeks 0-1): sensory disturbance with erythema and edema;
- Phase two (weeks 1-3): papulopustular eruptions;
- Phase three (weeks 3-5): crusting; and,
- Phase four (weeks 5-8): erythematotelangiectasias (red areas).

The lesions are usually sterile, but a secondary bacterial or fungal infection at the site of the eruption has been described in some cases. The severity of the rash waxes and wanes throughout these four phases, and typically resolves without permanent scarring within two months of therapy discontinuation, although scarring secondary to bacterial or fungal overgrowth can also occur.

The purpose of this document is to provide recommendations for the prevention and treatment of EGFR inhibitor therapy causing rash.

**Guideline Questions**

1. How should rash severity be graded?
2. What is the evidence for the relationship between rash and response to treatment in adult patients with advanced non-small cell lung cancer, colorectal cancer, head and neck cancers, or breast cancer treated with EGFR inhibitors?
3. What are the recommended strategies for the prevention of rash associated with EGFR inhibitor therapy in adult patients with advanced non-small cell lung cancer, colorectal cancer, head and neck, or breast cancers?
4. What are the recommended strategies for clinical management of rash associated with EGFR inhibitor therapy in adult patients with advanced non-small cell lung cancer, colorectal cancer, head and neck, or breast cancers?

**Search Strategy**

A literature search for articles about acneiform rash associated with the use of EGFR inhibitors in adult cancer patients was conducted at two different time points. The first literature search covered publications from 2000 to 2012 and informed recommendations in the original guideline published in
2012. The second literature search covered publications from 2012 to 2020 and informed updates to the original guideline. Existing guideline from other jurisdictions were identified during both search periods and reviewed by guideline working group members. In depth search criteria and selected articles/guidelines can be found in Appendix B.

**Target Population**

The recommendations outlined in this guideline apply to adult cancer patients treated with EGFR inhibitors (i.e. afatinib, cetuximab, erlotinib, gefitinib, lapatinib, osimertinib, panitumumab, pertuzumab) either alone or in combination with other treatments.

**Recommendations**

1. **Grading**

   a) Accurate grading of acneiform rash associated with EGFR inhibitors is essential to ensure timely and appropriate interventions. We recommend using the National Cancer Institute’s (NCI) Common Terminology Criteria for Adverse Events (CTCAE), which is the most widely used classification system in clinical trials.\(^{25}\) (Level of Evidence: V, Strength of Recommendation: C).

   CTCAE defines acneiform rash as a disorder characterized by an eruption of papules and pustules, typically appearing in face, scalp, and upper chest and back.

   **Table 2. NCI CTCAE v5.0 acneiform rash**

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Papule and/or pustules covering &lt;10% BSA*, which may or may not be associated with symptoms of pruritus or tenderness</td>
<td>Papules and/or pustules covering 10-30% BSA, which may or may not be associated with symptoms of pruritus or tenderness; associated with psychosocial impact; limiting instrumental ADL; papules and/or pustules covering &gt;30% BSA with or without mild symptoms</td>
<td>Papules and/or pustules covering &gt;30% BSA with moderate or severe symptoms; limiting self-care ADL; associated with local superinfection with oral antibiotics indicated</td>
<td>Life-threatening consequences; papules and/or pustules covering any % BSA, which may or may not be associated with symptoms of pruritus or tenderness and are associated with extensive superinfections with IV antibiotics indicated</td>
<td>Death</td>
</tr>
</tbody>
</table>

   **Abbreviations:** BSA=body surface area, ADL=activities of daily living, IV=intravenous

   *The simplest way to calculate BSA involvement is to use the patient’s palm. One palm is roughly equivalent to 1% BSA.*
2. Rash and Response to Treatment Relationship

a) Rash occurrence has been statistically associated with efficacy of EGFR targeted therapies.\textsuperscript{26-40} See Table 3 for a summary of key evidence. However, we cannot conclude from these studies that EGFR inhibitor therapy is ineffective if no or only mild rash occurs.\textsuperscript{41} (Level of Evidence: I, Strength of Recommendation: A)

b) The goal of all cancer treatment is to minimize toxicity, maximize treatment adherence, and maintain a good health-related quality of life. Therefore, before starting treatment with an EGFR inhibitor clinicians should explore patient tolerance for cutaneous side effects through a discussion that includes occurrence, timing, severity, prevention and management of acneiform rash.\textsuperscript{41-43} (Level of Evidence: V, Strength of Recommendation: B)

c) EGFR inhibitors should be administered at their maximum tolerable doses to obtain the most effective outcomes and should be accompanied with appropriate supportive care or preventive measures to counteract the rash.\textsuperscript{44, 45} (Level of Evidence: II, Strength of Recommendation: B)

Table 3. Summary of key evidence examining the relationship between rash and the efficacy of EGFR inhibitors

Results similar for E and G. • Association between risk of progression and skin rash statistically significant (HR: 0.50; 95% CI: 0.41–0.61; p&lt;0.00001. Results similar for E and G. • ORR ranged between 7% and 42% for patients with no rash and those with moderate to severe rash, respectively.</td>
</tr>
</tbody>
</table>

3. Prevention of Rash

a) Before starting treatment with EGFR inhibitors, clinicians should perform an assessment of patients for pre-existing cutaneous conditions (e.g. psoriasis, acne vulgaris, rosacea) that could worsen with exposure to EGFR inhibitors.<sup>46</sup> (<strong>Level of Evidence: V, Strength of Recommendation: B</strong>)

b) Patients should be informed about general skin care practices to prevent or reduce the severity of acneiform rash, including:<sup>46-48</sup> (<strong>Level of Evidence: II, Strength of Recommendation: B</strong>)

- Use alcohol-free emollients for overall skin moisturization (i.e. creams, ointments)
- Avoid popping acne pustules and using over-the-counter acne medications
- Adequately hydrate
- Apply broad spectrum (UVA, UVB) sunscreens before going outdoors and avoid excessive sun exposure
- Avoid hot water (i.e. use lukewarm water when showering, washing dishes)
- Avoid tight-fitting clothing or irritating fabrics (e.g. wool)

c) For most patients starting EGFR-inhibitor therapy, antibiotic prophylaxis can be used concomitantly with a topical steroid (1% hydrocortisone cream) for the first six weeks to reduce the incidence and severity of acneiform rash and improve quality of life.<sup>49-52</sup> In this role, the antibiotics are used for their anti-inflammatory properties and not their antimicrobial effects. We recommend
second-generation tetracyclines, either minocycline or doxycycline 100-200 mg daily (single or divided doses). While minocycline is less photosensitizing, doxycycline has a more favorable safety profile. See Table 4 for a summary of key evidence. (Level of Evidence: I, Strength of Recommendation: A) Although rare, for patients with allergies or intolerance to tetracyclines, erythromycin 500 mg twice a day or trimethoprim 160 mg/sulfamethoxazole 800 mg twice a day may be used as an alternative to minocycline or doxycycline. (Level of Evidence: V, Strength of Recommendation: C)

d) Studies have been unable to demonstrate a clinically significant benefit of adding tazarotene cream, dapsone gel, and vitamin K1 cream to minocycline or doxycycline. Similarly, topical erythromycin has not been shown to be an effective replacement for oral doxycycline, and therefore these drugs are not recommended. (Level of Evidence: II, Strength of Recommendation: C [dapsone, vitamin K1] and D [tazarotene, erythromycin])

Table 4. Summary of key evidence examining the use of prophylactic antibiotics for patients treated with EGFR inhibitors

<table>
<thead>
<tr>
<th>Author, year</th>
<th>Study type</th>
<th>Types of participants, N</th>
<th>Treatment</th>
<th>Outcomes</th>
</tr>
</thead>
</table>
| Petrelli, 2016 | Meta-analysis (randomized and retrospective) | NSCLC, GI, CRC, pancreatic, other N=1073 (13 studies) | Tetracyclines (tetracyclines in 3 studies, doxycycline in 4 studies and minocycline in 6 studies) | • In 12 studies, patients in prophylactic antibiotic arms had lower risk of developing skin rash (OR 0.53, 95% CI 0.39–0.72, P<0.01) than patients without antibiotic prophylaxis  
• Moderate-to-severe toxicities (Grade 2–4) reduced by nearly two-thirds (OR 0.36, 95% CI 0.22–0.60, P<0.01) in 13 studies; 26% absolute difference of high-grade skin rash compared with control arms (from 50% to 24%) |
| Bachet, 2012 | Meta-analysis (randomized) | Colorectal, lung, other, N=351 | Tetracyclines (doxycycline in 2 studies and minocycline in 2 studies) | • Combined odd ratio associated with incidence of folliculitis in each study was 0.19 (95% CI, 0.12-0.31; fixed effect model p<0.0001), indicating that the administration of a tetracycline in preventive therapy was associated with a significantly lower incidence of grade 2–3 folliculitis  
• Prophylactic tetracycline treatment also associated with an improvement in quality of life of patients in 3 of 4 studies in which this parameter analyzed |
4. Management of Rash

The management of acneiform rash induced by EGFR inhibitors is largely based on small-scale prospective trials, case reports and case series. As a result, management approach varies as shown in Appendix C which summarizes relevant guidelines and consensus statements published within the last 10 years. The recommendations presented below are a consensus of members of the Alberta Provincial Tumour Teams who have experience prescribing EGFR inhibitors and/or treating skin conditions (shown as pathway in Appendix A).

a) General recommendations. Overall management strategy for acneiform rash should be individualized and will depend on the type, severity, location and need to continue treatment. Consultation with a dermatologist is recommended, particularly for rash that does not improve within one to two weeks of treatment or if the patient is severely symptomatic. (Level of Evidence: II, Strength of Recommendation: B)

b) Grade 1 rash. Patients should continue EGFR-inhibitor therapy at the prescribed dose. We recommend treatment with topical clindamycin 2% plus hydrocortisone 1% lotion twice daily for four weeks. If after four weeks of treatment the rash has not improved or has worsened, patients should be treated for a Grade 2 rash. (Level of Evidence: V, Strength of Recommendation: C)

c) Grade 2 rash. Patients should continue EGFR-inhibitor therapy at the prescribed dose. We recommend treatment with topical clindamycin 2%, hydrocortisone 1% lotion plus either oral minocycline 100 mg twice daily or doxycycline 100 mg twice daily for four weeks, if not used prophylactically. If after four weeks of treatment the rash has not improved or has worsened, patients should be treated for a Grade 3-4 rash. (Level of Evidence: V, Strength of Recommendation: C)

d) Grade ≥3 rash. A dose reduction of EGFR-inhibitor therapy, as per label, may be required (see Appendix D). Obtain bacterial/viral culture if infection is suspected. We recommend treatment with topical clindamycin 2%, hydrocortisone 1% lotion plus either oral minocycline 100 mg twice daily or doxycycline 100 mg twice daily for four weeks, plus oral prednisone up to 0.5 mg/kg daily for seven to 14 days. Referral to a dermatologist is recommended if rash does not improve after four to eight weeks. (Level of Evidence: IV, Strength of Recommendation: C)

- If after four weeks of treatment the rash does not improve or worsens, low-dose isotretinoin (20 to 30 mg/d)\textsuperscript{57} or acitretin (25 mg/d)\textsuperscript{58} may be considered; evidence for its efficacy is however based on case series. (Level of Evidence: V, Strength of Recommendation: C)

- If the rash still does not improve or worsens despite dose modification and various treatment approaches (i.e. antibiotics, corticosteroids, isotretinoin, acitretin) discontinuation of EGFR inhibitor treatment may be necessary. (Level of Evidence: V, Strength of Recommendation: B)
e) **Secondary infection.** While pustules are generally sterile, secondary infection with bacteria, dermatophytes, or viruses may occur.\(^{20, 59, 60}\) Antibiotic selection for streptococcal or staphylococcal infections (culture proven with a swab), should be based on antimicrobial sensitivities. If pathogens other than streptococcal or staphylococcal are isolated, oncologists should ideally consult with a dermatologist for treatment advice (e.g. gram-negative microbes/other, saprophytic and dermatophyte fungi and yeasts). *(Level of Evidence: V, Strength of Recommendation: C)*

Appendix A: Treatment Pathway for Acneiform Rash in Patients Treated with EGFR Inhibitor Therapies

Patient taking EGFR inhibitor presents with rash

Assess severity of rash

Grade 1
- Topical clindamycin 2% plus hydrocortisone 1% lotion twice daily for 4 weeks
  - If no improvement or worsening of rash after 4 weeks

Grade 2
- Topical clindamycin 2% plus hydrocortisone 1% lotion plus either oral minocycline 100 mg twice daily or doxycycline 100 mg twice daily for 4 weeks, if not used prophylactically
  - If no improvement or worsening of rash after 4 weeks

Grade ≥3
- Dose reduction of EGFR inhibitor therapy, as per label, may be required
  - Obtain bacterial/viral culture if infection suspected
  - Topical clindamycin 2%, hydrocortisone 1% lotion plus either oral minocycline 100 mg twice daily or doxycycline 100 mg twice daily for four weeks, plus oral prednisone up to 6.5 mg/kg daily for seven to 14 days

Low dose isotretinoin (20 to 30 mg/d) or acitretin (25 mg/d) may be considered

If rash still does not improve or worsens despite dose modification and various treatment approaches discontinuation of EGFR inhibitor treatment may be necessary

If no improvement after 4-8 weeks refer to a dermatologist

General skin care practices to prevent or reduce the severity of acneiform rash

- Use alcohol-free emollients for overall skin moisturization (i.e. creams, ointments)
- Avoid popping acne pustules and using over-the-counter acne medications
- Adequately hydrate
- Apply broad spectrum (UVA, UVB) sunscreens before going outdoors and avoid excessive sun exposure
- Avoid hot water (i.e. use lukewarm water when showering, washing dishes)
- Avoid tight-fitting clothing or irritating fabrics (e.g. wool)

UK Expert Consensus of

- Continue EGFR TKI at current dose and apply emollient regularly
- Continue EGFR-TKI at current dose as rash improves
- Temporarily interrupt EGFR-TKI therapy
### Management of Adverse Events from EGFR Tyrosine Kinase Inhibitors

<table>
<thead>
<tr>
<th>Grade 1</th>
<th>Grade 2</th>
<th>≥ Grade 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>If signs of superadded infection, consider application of topical antibiotics in alcohol-free formulations for ≥14 days</td>
<td>Dose reduction or interruption appropriate if rash prolonged or intolerable</td>
<td>Restart EGFR-TKI therapy only when rash has improved to ≤ grade 2</td>
</tr>
<tr>
<td></td>
<td>If chronic grade 2 rash develops, consult with dermatologist</td>
<td>Dose reductions recommended for erlotinib and afatinib, but not for gefitinib</td>
</tr>
<tr>
<td></td>
<td>Intensify moisturizing; topical steroids can be applied on short-term basis (i.e. for 2–3 weeks)</td>
<td>Not uncommon in clinical practice to restart gefitinib on alternate days</td>
</tr>
<tr>
<td></td>
<td>Topical antibiotics (as alcohol-free formulations) and/or course of oral antibiotics (e.g. tetracycline ≥2 weeks) may be indicated</td>
<td>Manage rash as recommended for grade 2 with oral antibiotics + topical corticosteroids as appropriate and refer to dermatologist</td>
</tr>
<tr>
<td></td>
<td>Oral antihistamines can be prescribed for itchy rash</td>
<td>Identify and treat any potential infection associated with rash</td>

| **Targeted Anticancer Therapies** | • Topical antibiotics (2% clindamycin, 1% erythromycin cream, 0.75% metronidazole, 1% nadifloxacin)  
• Cream for isolated scattered lesions; lotion for multiple scattered areas | • Topical antibiotic + short-term topical steroid (e.g. 0.02% prednicarbacre cream) + oral antibiotic for at least 2 weeks  
• Doxycycline 100 mg BID or minocycline 100 mg BID | • Reduce EGFR inhibitor dose  
• Skin-type-adjusted moisturizer  
• Topical + systemic treatment, as per moderate rash  
• Refer to dermatologist  
• Consider oral isotretinoin or systemic steroids, but do not combine with oral tetracycline  
• Dose discontinuation + systemic steroids for life-threatening rash |
| Potthoff 2010<sup>64</sup>  
German Expert Panel EGFR inhibitor induced skin reactions | • Topical 2% clindamycin + 1% hydrocortisone lotion BID | • Topical 2% clindamycin + 1% hydrocortisone lotion BID  
• Oral minocycline 100 mg BID or doxycycline 100 mg daily or BID | • Withhold treatment until toxicity improves  
• Topical 2% clindamycin + 1% hydrocortisone lotion BID  
• Oral minocycline 100mg BID or doxycycline 100 mg daily or BID  
• If improvement seen, re-escalate dose; if no improvement, discontinue EGFR inhibitor treatment |
| Melosky 2009<sup>65</sup>  
Canadian Consensus Statement Management of Skin Rash During EGFR-Targeted Monoclonal Antibody Treatment for GI Cancer | • 2.5% hydrocortisone cream + doxycycline 100mg daily or minocycline 100 mg BID + prednisone 0.5 mg/kg x 5 days | • Topical 2% clindamycin + 1% hydrocortisone cream + oral antibiotic for at least 2 weeks  
• Doxycycline 100 mg BID or minocycline 100 mg BID |
Appendix D: Interruptions/Dose Reductions of EGFR Inhibitors for Patients with Persistent Rash

Afatinib:7
- Interrupt for up to 14 days until Grade 0/1 for prolonged or intolerable Grade 2 (≥7 days of rash). Resume with dose reduction by 10 mg decrements.
- Interrupt for up to 14 days until Grade 0/1 for any Grade ≥3. Resume with dose reduction by 10 mg decrements.

Cetuximab:9
- If patient experiences severe acneiform rash (Grade 3/4), adjust treatment according to table below.
- If rash improves and is no longer severe, resume treatment without any change in dose level.
- If severe acneiform rash recurs further interruption of therapy with dose reductions at pretreatment after improvement (initially to 200 mg/m² and subsequently to 150 mg/m²) or discontinuation of therapy may be required.

Erlotinib:66
- Patients with severe skin reactions may require a dose reduction or temporary interruption of therapy. When dose reduction is necessary, it is recommended to reduce in 50 mg steps.

Gefitinib:12
- Patients with skin adverse drug reactions may be successfully managed by providing a brief (up to 14 days) therapy interruption followed by reinstatement of the 250 mg daily dose once toxicity has resolved.

Lapatinib:14
- Consider discontinuation or interruption of dosing when patient develops toxicity Grade ≥2.
- Restart dosing at either 1250 mg/day when administered with capecitabine or 1500 mg/day when administered with letrozole, when the toxicity improves to Grade ≤1.
• If toxicity recurs, restart at a lower dose (1000 mg/day when administered with capecitabine and 1250 mg/day when administered with letrozole).

**Osimertinib:**

- Dose adjustments are not necessary for generally manageable adverse reactions.
- If dose reduction or modification is necessary based on individual safety and tolerability, then the dose should be reduced to 40 mg taken once daily.
- Dose reduction guidelines for adverse reactions toxicities are provided in the table below.

<table>
<thead>
<tr>
<th>Adverse Reaction</th>

**Pertuzumab:**

- Dose reductions not recommended for pertuzumab.
Development and Revision History
This guideline was reviewed and endorsed by members of the Alberta Provincial Thoracic Malignancies, Gastrointestinal, Head and Neck, and Breast Tumour Teams. Members of these Tumour Teams include medical oncologists, radiation oncologists, surgical oncologists, nurses, pathologists, and pharmacists. Evidence was selected and reviewed by a working group comprised of members from these three provincial Tumour Teams and a Knowledge Management Specialist from the Guideline Utilization Resource Unit. A detailed description of the methodology followed during the guideline development process can be found in the Guideline Utilization Resource Unit Handbook.

This guideline was originally developed in 2012. The guideline was revised and reposted in November 2020.

Levels of Evidence

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Evidence from at least one large randomized, controlled trial of good methodological quality (low potential for bias) or meta-analyses of well-conducted randomized trials without heterogeneity</td>
</tr>
<tr>
<td>II</td>
<td>Small randomized trials or large randomized trials with a suspicion of bias (lower methodological quality) or meta-analyses of such trials or of trials with demonstrated heterogeneity</td>
</tr>
<tr>
<td>III</td>
<td>Prospective cohort studies</td>
</tr>
<tr>
<td>IV</td>
<td>Retrospective cohort studies or case-control studies</td>
</tr>
<tr>
<td>V</td>
<td>Studies without control group, case reports, expert opinion</td>
</tr>
</tbody>
</table>

Strength of Recommendations

<table>
<thead>
<tr>
<th>Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Strong evidence for efficacy with a substantial clinical benefit; strongly recommended</td>
</tr>
<tr>
<td>B</td>
<td>Strong or moderate evidence for efficacy but with a limited clinical benefit; generally recommended</td>
</tr>
<tr>
<td>C</td>
<td>Insufficient evidence for efficacy or benefit does not outweigh the risk or the disadvantages (adverse events, costs, etc.); optional</td>
</tr>
<tr>
<td>D</td>
<td>Moderate evidence against efficacy or for adverse outcome; generally, not recommended</td>
</tr>
<tr>
<td>E</td>
<td>Strong evidence against efficacy or for adverse outcome; never recommended</td>
</tr>
</tbody>
</table>

Maintenance
A formal review of the guideline will be conducted during 2024. If critical new evidence is brought forward before that time, however, the guideline working group members will revise and update the document accordingly.

Abbreviations
BID, twice daily; CI, confidence interval; CRC, colorectal cancer; EGFR, epidermal growth factor receptor; GI, gastrointestinal cancer; HR, hazard ratio; IM, intramuscular; IV, intravenous; NSCLC, non-small cell lung cancer; OR, odds ratio; ORR, objective response rate; OS, overall survival; PFS, progression-free survival; QoL, quality of life; RR, risk ratio; TKI, tyrosine kinase inhibitor

Disclaimer
The recommendations contained in this guideline are a consensus of the Alberta Provincial Supportive Care Tumour Team and are a synthesis of currently accepted approaches to management, derived from a review of relevant scientific literature. Clinicians applying these guidelines should, in consultation with the patient, use independent medical judgment in the context of individual clinical circumstances to direct care.
