Alberta Health Services is committed to the protection, promotion, and support for breastfeeding. Breastfeeding is the normal and unequalled method of feeding infants. (1) Exclusive breastfeeding for the first 6 months, and continued for up to 2 years or longer, is recommended for the healthy growth and development of infants and toddlers. (1) This document is intended for professional reference only when advising those who cannot breastfeed and those that have made an informed feeding decision not to breastfeed or to partially breastfeed.

Updated by Nutrition Services, Alberta Health Services
Product information for all infant formulas for healthy term infants available in Alberta was obtained from nutrition labels through store visits in various communities in Alberta or from manufacturer websites and is current as of January 8, 2018. If you question the appropriateness of a product, contact your local Registered Dietitian.

Overall Recommendations

This document was prepared with the full recognition that breastmilk is the normal and unequalled food for infants. This document provides information on commercial infant formula and is intended for professional reference only when advising those who cannot or have made an informed decision not to breastfeed or to partially breastfeed.

Homemade infant formulas are not recommended as an alternative to breastmilk or commercial infant formula as they may:
- be nutritionally incomplete (2,3)
- deliver a high renal solute load (2,3)
- increase food safety risk (3)
- exceed recommended levels of some vitamins or minerals (3)

For more information refer to the Nutrition Guideline: Homemade Infant Formula.

Commercial infant formula sold in Canada will meet the nutrition needs of infants and is the only recommended alternative to breastmilk for infants younger than nine months of age. All commercial infant formulas undergo a full safety and nutritional quality assessment before they can be sold in Canada. (4) All manufacturers, importers and distributors of infant formula are responsible to ensure their products comply with Canadian legislation. (4)

Caution regarding infant formula produced outside of Canada. Health Canada cautions against the purchase of infant formula from internet sites or from other countries. (5) There is no clear way to confirm if formulas purchased on the internet or outside of Canada meet Canadian safety and nutrition guidelines.

Some commercial infant formulas have a product number which can be used for claiming on health insurance or Income Support programs (e.g. Extensively Hydrolyzed Casein Formulas). Commercial infant formulas are classified as a food, not a drug and therefore do not have a Drug Identification Number (DIN).

For more information on infant formula labelling, safety, and recalls see the Health Canada Food and Nutrition page at http://www.hc-sc.gc.ca/contact/fn-an/index-eng.php#3.

When reconstituted, the nutrition content of powder, liquid concentrate or ready-to-feed infant formulas is very similar. Powdered infant formula (PIF) is not sterile, but can be safely used for healthy full term infants when prepared and handled appropriately. (6) Liquid concentrate or ready-to-feed formulas are recommended for infants at greatest risk of infection i.e., pre-term or low-birth weight who are less than 2 months (postnatal age) or immunocompromised. (2,6) Where nutritionally appropriate liquid infant formula is not available, PIF may be recommended by the infant's healthcare provider. Parents are advised to follow AHS guidelines for preparing infant formula and to follow the manufacturer’s instructions (on the formula can label) for the amount of infant formula and water to use. For more information refer to the Nutrition Guideline: Safe Preparation and Handling of Infant Formula. In emergency response situations, additional safety precautions may be needed.
A daily 400 International Unit (IU) vitamin D supplement is recommended for all healthy term infants. This applies to exclusively breastfed, partially breastfed and formula fed infants. For more information refer to the Nutrition Guideline: Vitamin D.
Comments on Infant Formula Composition

Allergy Prevention
Breastfeeding is the normal feeding method for infants at high risk of allergy. (7-9) There is no evidence to support giving hydrolyzed infant formula over exclusive breastfeeding to prevent allergies. (7) For infants who are not breastfed or are partially breastfed and are at high risk of allergy (at least one first-degree relative with a diagnosed atopic disease such as atopic dermatitis, asthma, allergic rhinitis, or food allergy), there is limited evidence that feeding with a hydrolyzed formula (i.e. extensively hydrolyzed casein infant formula or a partially hydrolyzed 100% whey infant formula) as compared to a standard cow's milk formula, can help reduce the risk of allergic disease, particularly eczema (7, 8, 10-15), if used for the first 6 months of life. (9, 14, 16, 17) More research is needed to conclude how these types of infant formulas compare in terms of allergy prevention. (7, 11, 18-20) Parents may select a hydrolyzed formula based on selections available. Evidence does not support using extensively or partially hydrolyzed protein infant formula after 6 months for allergy prevention. (9, 16, 17) For more information refer to the Nutrition Guideline: Allergy Prevention.

Allergy Treatment
For an infant with a diagnosed allergy to cow's milk protein, encourage and support a breastfeeding mother to continue breastfeeding; the mother may need to avoid all sources of cow's milk protein in her diet. (21) If this is the case, nutrition counselling by a Registered Dietitian is recommended. (21)

For non-breastfed or partially breastfed babies, extensively hydrolyzed casein infant formulas are the first choice in the treatment of cow's milk protein allergy. (22) (See Extensively Hydrolyzed Casein Formulas section for more information).

Some infants with a cow's milk protein allergy may not tolerate an extensively hydrolyzed casein formula and may require an amino acid-based formula. (21) (See Amino Acid-based Formulas section for more information)

Soy infant formula may be a second option for infants older than 6 months if a tolerance to soy has been established. (21) (See Soy Formulas section for more information).

DHA and ARA
DHA (docosahexaenoic acid) and ARA (arachidonic acid) are long-chain polyunsaturated fatty acids (LCPUFA) that are essential for maturation of the developing brain, retina and other organs in newborn infants. (23, 24) DHA, ARA and their precursors are found naturally in breastmilk. (25) The preferred source of nutrition for infants is breastmilk, and the availability of infant formulas with DHA and ARA does not change this recommendation. (26)

Standard infant formulas do not contain DHA and ARA; they contain the essential fatty acids alpha-linolenic acid and linoleic acid from which formula-fed infants synthesize their own DHA and ARA, respectively. (24) Some infant formula manufacturers add DHA and ARA directly to infant formulas. These are typically labeled as ‘omega 3 and omega 6’ on formula packaging and are marketed as providing an advantage.
for infant development. As the addition of DHA and ARA is not mandatory in Canada (22); there are no Canadian guidelines that specify levels of DHA and ARA to be added. (27) Infant formulas with added DHA and ARA currently cost more than the same infant formula without added DHA and ARA.

For term infants, adding DHA and ARA to infant formulas may provide possible benefits for visual and neurodevelopmental outcomes, but results are inconsistent. (26) There are no studies which report negative side effects of consuming an infant formula with added DHA and ARA. Based on the potential benefits, and no known adverse effects, parents may select to provide a formula with added DHA and ARA based on selections available and their financial means. However, at this time the evidence is not strong or consistent enough to make a public health recommendation for routine and compulsory DHA and ARA supplementation for formula-fed term infants. (24)

For preterm infants who are not breastfed or require supplementation of breastmilk and are not discharged home on Post Discharge Preterm Formula (PDPF), a term infant formula with iron and DHA and ARA is recommended. (28) For more information refer to the *Nutrition Guideline: Post-discharge Preterm Formula (PDPF)*.

**Iron Fortification**

Iron deficiency is the most common micronutrient deficiency worldwide. Young children are a special risk group because their rapid growth leads to high iron needs. (29) The amount of iron needed to prevent iron deficiency is controversial and needs more research. In Canada, commercial infant formulas for healthy term infants currently contain levels of iron of 6.5 to 13 mg/L and are acceptable for most healthy term infants. (22) Formulas with iron at the lower levels should be sufficient for most healthy term infants. (30,31)

For infants at risk of iron deficiency, it is prudent to recommend infant formula with iron levels at the higher end of the range (eg.10 – 13mg/L). (30) Infants at risk of iron deficiency include infants with a birth weight of less than 3000 grams; those born to iron deficient mothers, mothers with diabetes, or mothers who consumed excess alcohol during pregnancy; or infants not fed according to current recommendations (e.g. Infants started on complementary foods prior to 6 months, infants whose first foods were not iron rich). (22)

**Organic Formulas**

Within this document, infant formulas certified as organic have received organic certification from a certification body accredited by the Canadian Food Inspection Agency (CFIA). (32) The organic certification does not represent specific claims about the health, safety and nutrition of the organic product. (33) While organic infant formulas are safe and acceptable choices, current evidence does not identify any health advantages to choosing organic food products over non-organic food products. (34,35) Parents may select an organic infant formula based on the options available and their preference for this food production method.

**Nucleotides**

Although human bodies are able to produce nucleotides, dietary sources of nucleotides may be important during periods of rapid growth or illness. (36) Currently, nucleotides may be added to commercial infant formulas, but are not mandatory. Some studies have shown that
adding nucleotides to infant formulas may have potential health benefits, such as improved maturation of the immune system and a decreased incidence of diarrhea. (37) However, most supplemented infant formulas do not contain the levels most research studies have associated with potential health benefits. (37) More research is still needed to show that adding nucleotides to infant formulas consistently leads to health benefits, and to identify the optimal level of supplementation. Because of possible benefits and lack of adverse effects, parents may select infant formulas with added nucleotides based on the options available.

**Palm Olein (PO)**

Fat sources in commercial infant formulas vary and include a mix of soy, coconut, sunflower, and safflower oils. Palm olein (PO) from fractionated palm oil is added to some infant formula to create a fat profile with 23% palmitic acid and 34% oleic acid, the same ratio found in human milk. No growth or weight gain differences have been observed in infants consuming formula containing PO. (38) However, due to structural differences, the added PO results in insoluble fatty acids that form poorly absorbed salts that are excreted in stool, causing stools to be firmer, greener in colour, and less frequent. (39,40).

Not all infant formulas contain PO; parents may select infant formulas based on the options available. As the addition of PO to infant formulas may cause hard/ firm stools, (41) it may be worthwhile for infants with hard stools to try an infant formula that does not have PO added.

**Standard Cow’s Milk Formulas**

Commercial cow’s milk-based infant formulas are the standard choice for healthy term infants who are not exclusively breastfed. (22, 31) Standard cow’s milk infant formulas are not suitable for use for cow’s milk protein allergy, galactosemia, or for those who cannot consume dairy-based products for cultural or religious reasons. (22)

**Partially Hydrolyzed Protein Formulas**

There are two different types of partially hydrolyzed protein infant formulas, and the indications for use differ between the two.

- **Partially Hydrolyzed Protein, Lactose-Reduced Formulas**
  These infant formulas have reduced lactose levels and contain partially hydrolyzed whey and casein proteins, (42,43) These infant formulas are marketed as “Easy to Digest” or for infants with fussiness and gas. (42,43) There is insufficient evidence identifying a need for these infant formulas in reducing colic. (44) In addition, evidence does not support using a partially hydrolyzed infant formula, containing both casein and whey proteins, for allergy prevention. (45) Partially hydrolyzed protein, lactose-reduced infant formulas are considered safe and acceptable choices; however, based on current evidence, there is no clear indication for the use of these infant formulas for most healthy term infants. (46) The only time lactose reduced infant formulas may be justified is for situations of severe dehydration, malnourishment, severe enteropathy, or when lactose-containing formula worsens the condition, such as with confirmed lactase deficiency. (46) Current lactose reduced formulas contain only 20-25% of the lactose of the standard cow’s milk based formulas. (43,47)
• **Partially Hydrolyzed 100% Whey Formulas**
These infant formulas contain partially hydrolyzed whey protein. There is some evidence that for infants at high risk of allergy, who are not exclusively breastfed, using a partially hydrolyzed 100% whey infant formula instead of a standard cow’s milk infant formula in the first 6 months of life may reduce the risk of developing an allergy. (7,12,13,19) See Allergy Prevention section for more information.

**Formulas with Prebiotics**
Prebiotics are nondigestible food components that selectively stimulate growth and/or activity of one or a limited number of bacterial species in the colon, and thereby improve host health. (48) Prebiotics studied for use in infant formula include galacto-oligosaccharides (GOS), polydextrose (PDX), fructooligosaccharides (FOS), lactulose, inulin, as well as various combinations. (49) Currently, GOS and PDX are the only prebiotics added to commercial infant formulas in Canada.
Formula fed infants not yet introduced to complementary foods experiencing hard stools may benefit from consuming an infant formula supplemented with GOS (4g/L) or PDX/GOS blend (2g/L PDX and 2g/L GOS). (50-52) While some prebiotic infant formulas in Canada have 4.0g/L of prebiotic GOS or PDX/GOS blend added, some contain lower dosages. Lower dosages of GOS in formula (e.g. 2.9 g/L) have not been studied and therefore, it’s unknown if these formulas will also improve stool consistency. Further research is needed before it can be recommended that prebiotics are needed in infant formula. For more information refer to the Nutrition Guideline: Prebiotics and Probiotics.

Parents may select an infant formula with prebiotics based on the options available. It may be worthwhile for infants with hard stools to try an infant formula that contains 4.0g/L of prebiotics.

**Formulas with Probiotics**
Probiotics are live microorganisms which, when consumed in adequate amounts, confer a health benefit on the host. (53) When specific strains are consumed at proper doses, probiotics can have potential health benefits (54) for infants. (55,56) More research is needed to determine the best dose, strain and duration. (57) *Bifidobacterium animalis* subsp *lactis* (B. lactis) (58) and *Lactobacillus rhamnosus* GG (LGG) are 2 probiotics currently available in infant formulas. (59)
Although current infant formula supplemented with probiotics is safe for healthy term infants, (55,60) further studies are required before it can be recommended that probiotic cultures are needed in infant formula. Parents may select an infant formula with probiotics based on the options available. More research is needed regarding the safety of probiotics in vulnerable groups such as premature and low birth weight infants.

For more information refer to the Nutrition Guideline: Prebiotics and Probiotics.

**Follow-Up Formulas**
Cow’s milk follow-up infant formulas are not suitable for infants younger than 6 months, (61) or for infants with a cow’s milk allergy, lactose intolerance or galactosemia.
Follow-up or second stage infant formulas, which are designed for infants 6 months of age and older who are eating solid foods, (62) contain higher amounts of calcium and phosphorus than starter infant formulas because calcium needs increase for the second 6 months of life. (62-64) However, follow-up formulas do not offer any nutrition or health benefits over infant formula and are not recommended. (63)

Infants begin to eat solid foods at 6 months and therefore calcium and phosphorus needs should be met from standard (starter) infant formulas and food sources. (63) Pasteurized 3.25% milk may be introduced to infants 9-12 months of age, who eat iron-rich foods at most meals, and continued throughout the second year of life. (62)

Toddler nutritional supplements (e.g. Enfagrow® 3, Go and Grow 3, Good Start 3, and Parent’s Choice or President’s Choice Toddler 3) are not included in this document. These toddler drinks are not the same as follow-up or second stage infant formulas, and are inappropriate for infants under 12 months of age. (65) Toddler drinks, which are marketed as an alternative or complement to breastmilk or cow’s milk for children older than 12 months of age, have added sugars and are not needed. After 9 -12 months, a child can transition directly to 3.25% milk. (62) If parents offer toddler drinks instead of 3.25% milk, advise them to ensure the product contains calcium, vitamin D, vitamin A, protein, and fat, in comparable amounts to the 3.25% milk. If parents provide these toddler drinks due to a nutrition concern, a referral to a Registered Dietitian is recommended.

Infant Formulas with Other Considerations

When an infant past one year of age needs to continue on an infant formula for a special condition, encourage parents to provide calcium-rich foods as many of these infant formulas contain less calcium than whole milk. (66) Referral to a Registered Dietitian for related resources and further information is recommended.

Soy Formulas

There are limited indications for feeding soy formulas to healthy term infants. These indications include the management of infants with galactosemia or primary lactase deficiency, and infants who cannot consume dairy-based products for cultural, ethical or religious reasons, such as a vegetarian lifestyle. (67)

The use of soy infant formulas is contraindicated for non-IgE-mediated cow’s milk protein allergy (CMPA) due to the high rate of coincident soy allergies. (67,68) If a non-IgE mediated CMPA can be satisfactorily ruled out, then the use of soy infant formula is an acceptable alternative as the coincident soy allergy for IgE mediated CMPA is much less frequent. (67) However, from a public health standpoint, until a non-IgE mediated CMPA can be satisfactorily ruled out it is safer and more appropriate to recommend an extensively hydrolyzed casein infant formula to treat infants with CMPA (67,68) especially in infants younger than 6 months of age. (68,69) Soy infant formulas may be considered for therapeutic use after 6 months of age (68-71) if a tolerance to soy protein has been established under physician guidance. (70) Infants with documented cow’s milk protein-induced enteropathy or enterocolitis are often sensitive to soy protein and should not be given soy formulas. (72)

Soy-based infant formulas have been used in North America for over a century, (73) and have been shown to support normal growth and development in term infants. (68,72,74) The patterns of growth, bone health, reproductive, endocrine, immune and neurological functions are
similar to those observed in children fed cow’s milk infant formula or human milk. (75) No overt harm has been proven with the use of soy-based infant formulas with the exception of preterm infants, infants with congenital hypothyroidism, (68) and infants with renal failure. (75)

Opponents of soy infant formula counter that the safety of soy infant formula has not been rigorously tested, particularly health effects associated with the phytoestrogens in soy products. (73) Soy infant formulas contain phytoestrogens called isoflavones (68) which are non-steroidal chemicals that are structurally similar to estrogens. (76) Some studies found that most of the phytoestrogens present in soy infant formula are in a conjugated form and therefore are unable to exert hormonal effects. (75) A lack of evidence is available to suggest that soy infant formulas adversely affect endocrine function, development or reproduction in infants. (68,72) As such, further research is warranted and use of soy infant formulas should be limited to the indications described above. Soy infant formula has no proven value in the prevention or management of infant colic. (72)

Soy infant formula is not appropriate for:
(a) Soy protein allergy
(b) Prevention of allergy in healthy term infants at high risk of allergy. (77)
(c) Preterm infants. Soy infant formulas have high aluminum content and aluminum toxicity may develop in preterm infants due to their reduced renal function. (75) As aluminum competes with calcium for absorption, this may result in reduced skeletal mineralization (osteopenia). (75) Serum phosphorus concentrations are lower, and alkaline phosphatase concentrations are higher in preterm infants and infants with intrauterine growth restriction (IUGR) fed soy infant formula, compared to preterm infants fed cow’s milk infant formula. Therefore, the degree of osteopenia is increased in infants with low birth weight receiving soy infant formulas. (72)
d) Congenital hypothyroidism. Infants with congenital hypothyroidism fed soy infant formula need close monitoring due to reported abnormal thyroid function. This does not appear to be a concern in infants with healthy thyroid function. (70)

Note: The vitamin D in soy infant formula is from an animal source. This information is important to share with vegan families. (67)

Soy Follow-Up Formulas
Following or second-stage infant formulas, which are intended for infants 6 months of age and older who are eating solid foods, (62) contain more calcium and phosphorus than starter infant formulas as needs for these nutrients are higher for older infants. (64) When infants need to continue on a soy-based formula, a soy follow-up formula is recommended by 12 months of age to help meet calcium needs. A soy follow-up formula is advised until 2 years of age at which time a child can then transition to a fortified plant-based beverage, such as a soy beverage. Soy follow-up formulas, if consumed in recommended amounts (500 mL per day), may not contribute enough calcium to meet the calcium requirements of a 1-year old. (64) Therefore, other calcium-rich foods will also need to be emphasized and consultation with a Registered Dietitian may be beneficial.

Lactose-Free Formulas
Lactose-free infant formulas are not suitable for infants with congenital lactase deficiency, a rare disorder, or galactosemia as these infant formulas may contain residual galactose. (22) Lactose-free infant formulas are also not suitable for infants with cow’s milk protein allergy and are ineffective in the dietary management of infant colic. (22)
Lactose-free infant formula was previously recommended for infants with diarrhea and gastroenteritis because of possible small intestinal injury during such illness. Breastfeeding during acute diarrhea is still recommended and is well tolerated in spite of its higher lactose content compared to most cow’s milk infant formulas. Breastmilk is often provided as smaller, more frequent feedings than infant formula and this may decrease the lactose load delivered per feed, resulting in enhanced absorption. (46) The use of lactose-free infant formula during acute diarrhea is not justified in most cases. (2,46) Enough lactose digestion and absorption are typically preserved in acute gastroenteritis that low lactose and lactose-free infant formulas do not have clinical advantages over lactose-containing infant formulas. (22,46) If dehydration has been treated, or if mild to moderate dehydration is present, lactose-free infant formulas are not indicated. (2,46) If severe dehydration, malnutrition, or severe enteropathy exist, or when a lactose-containing infant formula worsens the condition (confirmed lactase deficiency) then the use of a lactose-free or low lactose infant formula by formula fed infants may be justified. (2,46)

Extensively Hydrolyzed Casein Formulas
Extensively hydrolyzed casein infant formulas are intended for infants who have diagnosed food allergies (22,79,80) including cow’s milk (80) or soy protein, or for specific malabsorption problems. (22)

For infants who are not breastfed or are partially breastfed and are at high risk of allergy (at least one first-degree relative with a confirmed allergy diagnosed atopic disease such as atopic dermatitis, asthma, allergic rhinitis, or food allergy), some research shows an extensively hydrolyzed casein infant formula may reduce the risk of developing an allergy (compared to a standard cow’s milk formula) if used for the first 6 months of life. (7,13,16,17) See Allergy Prevention section for more information.

Amino Acid-Based Formulas
Amino acid-based infant formulas are designed for infants with a cow’s milk allergy and multiple food protein intolerances who cannot tolerate extensively hydrolyzed casein infant formulas. (81,82) Amino acid-based infant formulas should be used under medical direction and only in infants with extreme cow’s milk allergies who cannot tolerate extensively hydrolyzed casein formulas. (83) Amino acid-based infant formulas have not been used for allergy prevention; (17) they have higher cost, poor palatability and limited availability.

Infant Formulas that Become Thickened
Regurgitation (spitting up) is normal in infancy and only rarely leads to health problems such as failure to thrive. In infants, regurgitation reflects physiological immaturity, usually improves without any medical intervention, (84) becomes less frequent with time, and resolves in 90% of infants before 1 year of age. (85) Further assessment is needed if regurgitation persists or increases in severity. (22) As a milk protein allergy is sometimes a cause of vomiting in infants, formula-fed infants with recurrent regurgitation and vomiting may benefit from a 2 – 4 week trial of an extensively hydrolyzed formula. (86)

Gastroesophageal reflux (GER), with or without regurgitation is relatively common in healthy term infants with regurgitation occurring daily in approximately 50% of infants three - four months of age. (22,86) Education on feeding position modifications and feeding changes, anticipatory guidance, and support are usually sufficient to manage healthy, thriving infants with physiologic GER. (86) Formula that thickens
in an infant’s stomach is intended for infants with mild GER, and should be used only when recommended by a physician. Thickened infant formula does not decrease frequency of reflux episodes but may decrease visible regurgitation which may improve quality of life for caregivers. (86) This infant formula is not intended for infants who need specialized thickened formula due to swallowing difficulties. It is not recommended to thicken infant formula with infant cereal (22) as this may increase coughing during feeding and may increase the energy density of the formula causing excessive energy intake. (86)

**Post-Discharge Formulas for Preterm Infants**

Post-discharge infant formulas for preterm infants have been specifically designed to meet the needs of preterm and low-birth weight infants after discharge from a hospital and should only be used with the advice of a physician or dietitian. For more information on these infant formulas refer to the *Nutrition Guideline: Post-discharge Preterm Formula*. 

Other Milks

Cow’s Milk

3.25% Homogenized Milk
3.25% milk is not recommended for infants before 9-12 months of age as it increases the risk of iron-deficiency anemia (due to low iron content, displacement of iron rich foods, and inhibition of iron absorption) (45) and has smaller amounts of essential fatty acids and other essential nutrients than breastmilk. (62,22,87) Cow’s milk contains a less digestible form of protein (22) and may cause occult blood loss in infants less than 6 months of age. (88,89)

3.25% cow’s milk is appropriate for infants after 9-12 months of age who are eating iron-rich solid foods at most meals, and continues to be recommended for the second year of life. (62)

Partly Skimmed (2%, 1%) and Skim Cow’s Milk
Lower fat milks are not appropriate milk sources before 2 years of age because they provide inadequate energy and essential fatty acids. (62) They are not recommended for children under 2 years of age unless under the supervision of a physician or dietitian.

Goat’s Milk

Whole goat’s milk
As with 3.25% cow’s milk, whole goat’s milk is not recommended for infants before 9-12 months of age because it is low in iron, low in essential fatty acids and other nutrients, and contains a less-digestible form of protein. (62) Fortified whole goat’s milk may be offered in place of cow’s milk for infants 9-12 months of age who are eating iron-rich foods at most meals. (62,90)

Pasteurized, whole goat’s milk is available at grocery stores in Alberta, however it is hard to find goat’s milk that is fortified with recommended amounts of vitamin D and folic acid. Children consuming non-fortified whole goat’s milk may not meet their daily vitamin D requirements. Advise parents who offer non-fortified goat’s milk to consult with their child’s doctor or dietitian to see if their infant needs more than the 400 IU Vitamin D supplement recommended for all children.

Although unfortified goat’s milk is low in folic acid, infants 9 – 12 months of age can get folate in their diet by eating foods such as vegetables (especially dark green vegetables), fruits, beans, poultry and meat, eggs, seafood, and grains.

Goat’s milk is not recommended for cow’s milk allergy or for lactose intolerance. Cow’s and goat’s milk are very similar in composition in terms of their protein, fat and carbohydrate content. (91) Due to the similarity in proteins, older infants and young children who have a food allergy to cow’s milk protein are also likely to have an allergic reaction to goat’s milk. (62,90)
Partly Skimmed Goat’s Milk
As with cow’s milk, lower fat goat’s milk is not appropriate before 2 years of age. For more information on cow’s and goat’s milk refer to the Nutrition Guideline: Milk

Soy and Other Plant-Based Beverages
Plant-based beverages are not appropriate alternatives to breastmilk, 3.25% milk, or commercial infant formula in the first 2 years of life as they are generally lower in protein, fat, calories and iron. (3,62)
For children 2 years of age and older not consuming breastmilk, 3.25% milk, or commercial infant formula, Eating Well with Canada’s Food Guide recommends a fortified soy beverage. (92) If parents choose another plant-based beverage as the main milk source for their child, advise them to look for a product that:
- provides at least 6 g of protein per 250 mL (1 cup) (93)
- provides at least 30% Daily Value of calcium and vitamin D per 250 mL (1 cup); and (93)
- contains less than 10g of sugar per 250 mL (1 cup). (94)

For more information refer to the Nutrition Guideline: Plant-Based Beverages.
Infant Formulas – Product Listing

This information is for professional reference only. The type of protein, fat and carbohydrate is based on powder format unless otherwise specified. It is current as of January 8, 2018. Alberta Health Services does not endorse or recommend any specific commercial infant formula products.

Glossary

**Allergy:** An allergy is an inappropriate or exaggerated reaction of the immune system to otherwise harmless substances that, in the majority of people, cause no symptoms. It is applied to all types of immunologically-mediated hypersensitivity reactions. (95)

**Casein:** Casein is the main protein in milk. (96) Milk protein fractions are subdivided into casein and whey proteins. The caseins constitute ~76–86% of the protein in cow’s milk. (97)

**Certified organic:** Infant formulas certified as organic in this document have received organic certification from a certification body that has been accredited by the Canadian Food Inspection Agency (CFIA) to certify organic products; or that is recognized under an organic trade arrangement with a foreign competent authority under the *Organic Products Regulations, 2009*. (32) The organic certification does not represent specific claims about the health, safety and nutrition of the organic product. (33)

**Colic:** Periods of irritability, fussiness, or crying that start and stop without obvious cause and with no evidence of failure to thrive. (22) A commonly used definition of colic is that the episodes last three or more hours per day and occur at least three days per week for at least one week. (98) Infant colic typically starts before three to four weeks of age and resolves by four months. (22)

**Congenital lactase deficiency:** Inborn error of metabolism in which the lactase enzyme is absent or severely reduced at birth. It is an extremely rare disorder. (99)

**Docosahexaenoic Acid (DHA) and Arachidonic Acid (ARA):** These are long-chain polyunsaturated fatty acids that have a role in brain and retina development. (22) DHA is an omega 3 fatty acid. ARA is an omega 6 fatty acid.

**Extensively hydrolyzed casein protein formula:** is a formula where the proteins have been hydrolyzed (“digested”) by enzymatic activity to yield single amino acids and small peptides to achieve a product that has few proteins capable of initiating an immunological response. (100)

**Follow-up formulas:** Follow-up or second-stage infant formulas are formulas intended for infants 6 months of age or older who are consuming solid foods. (61,62)

**Galactosemia:** Lactose in food is broken down by the body into glucose and galactose. Galactosemia is a rare genetic condition of carbohydrate metabolism in which a blocked or inactive enzyme does not allow breakdown of galactose, causing serious illness in infancy. (101)

**Gastroesophageal reflux:** is the passage of gastric contents into the esophagus, with or without regurgitation (“spitting up”). (22)

**GOS (galactooligosaccharide):** A non-digestible dietary fibre; a prebiotic that selectively stimulates the growth and/or activity of one or more bacteria in the colon and thus improves host health. (102)
**Halal:** Halal is an Arabic term meaning “permitted, allowed, lawful, or licit” when used in relationship to food or drink means permissible for consumption by a Muslim. (103) Food is determined to be Halal based on how it is obtained, processed and other factors. (103)

**High allergy risk:** at least one first-degree relative (parent or sibling) with a diagnosed atopic disease (such as atopic dermatitis, asthma, allergic rhinitis, or food allergy)

**Hypoallergenic:** means "less allergenic." Some experts consider an infant formula hypoallergenic if it can be tolerated by 90% of the individuals allergic to the parent protein (e.g. cow's milk or soy protein). (104)

**Kosher:** In Hebrew, kosher means “fit” or “proper”. Food is Kosher or acceptable to eat, when prepared in accordance with the conditions set by Judaic law. (103)

**Lactose intolerance:** the inability to digest lactose into the monosaccharides glucose and galactose for absorption due to low levels of lactase enzyme in the brush border of the duodenum. There are three types of lactase deficiency: congenital, primary, and secondary. (99)

**MCTs:** Medium chain triglycerides are shortened fatty acids that are effectively absorbed by infants with fat malabsorption. (105)

**Nucleotides:** Nucleotides are molecules that, when joined together, make up the structural units of ribonucleic acid (RNA) and deoxyribonucleic acid (DNA). (106) Nucleotides play key roles in many biological processes and are suggested to be conditionally essential nutrients in infancy. (36)

**Partially hydrolyzed protein formula:** infant formula which has a portion of the cow’s milk protein partially broken down.

**Phytoestrogens:** non-steroidal chemicals which are structurally similar to estrogens. (76)

**Prebiotics:** Prebiotics are nondigestible food components that beneficially affect the host by selectively stimulating the growth and/or activity of one or a limited number of bacteria in the colon and thereby improving host health. (56)

**Probiotics:** Probiotics are live microorganisms which, when administered in adequate amounts, confer a health benefit on the host. (53) Probiotics can have potential health benefits (54) for infants (55,56) if specific strains are consumed at proper doses. (54)

**Regurgitation (spitting up):** the passive movement of stomach contents into the pharynx or mouth. (107)

**Whey to casein ratio:** Whey and casein are two milk proteins. The whey to casein ratio represents the relative amounts of these two milk proteins in each type of infant formula.
