AN INTRODUCTION TO KNOWLEDGE TRANSLATION IN HEALTHCARE

What is Knowledge Translation?

Despite the high demand for knowledge translation (KT) activities in healthcare, there is no clear and consistent definition of KT. A number of different terms, including knowledge transfer, knowledge exchange, research utilization, and evidence implementation are used interchangeably to describe the concept of moving research into practice. Informally, KT is described as closing the gap between what we know and what we do (Graham & Tetroe, 2009). The Canadian Institutes of Health Research (CIHR) define KT as:

[A] dynamic and iterative process that includes synthesis, dissemination, exchange and ethically sound application of knowledge to improve the health of Canadians, provide more effective health services and products and strengthen the healthcare system. This process takes place within a complex system of interactions between researchers and knowledge users... (n.d., p. 1)

Under this widely adopted definition, a diverse range of activities fall under KT, including technology transfer, knowledge management, knowledge use, continuing education, and consensus guideline development (Goldner et al., 2014; Strauss, Tetroe, & Graham, 2011).

The goal of KT is to ensure that individuals at all levels of the health system (patients, health professionals, and policy makers) can “…access and use research evidence to inform health-related decision making” (Strauss et al., 2011, p. 7).

Why is Knowledge Translation Important?

A significant gap exists from the time new knowledge is created to when it is put into practice (Lang, Wyer, & Haynes, 2007). It is estimated that after an average of 17 years only 14% of research findings are translated into practice (Ammerman, Smith, & Calancie, 2014). This gap highlights the challenge in translating promising research findings and health interventions into action. When new knowledge fails to translate into action, or occurs over a long period of time, health professionals, patients, and policy makers are unable to access current, best quality evidence (Strauss et al., 2011). KT seeks to bridge this gap by linking knowledge producers and knowledge users to maximize the potential of new knowledge (Goldner et al., 2014; CIHR, n.d.).

The area of addiction and mental health (AMH) is replete with myths and misinformation that can lead to stigma and discrimination among the general public and health professionals towards people with AMH conditions (Angermeyer & Dietrich, 2006; Ross & Goldner, 2009). Effective KT approaches can play an important role in facilitating the transfer, uptake, and use of high quality evidence to improve health outcomes and help end the stigma around AMH (Goldner et al., 2014).
The Knowledge-to-Action Cycle

There are a number of conceptual frameworks and theories for achieving KT. One of the most widely used frameworks is the knowledge-to-action cycle developed by Graham et al. (2006), which has been adopted by the CIHR. The framework describes the process from knowledge creation to application (action cycle) (Strauss et al., 2011). The knowledge creation funnel, found in the centre of the figure below, shows the three stages of knowledge creation: 1) knowledge inquiry (the production of knowledge, e.g., primary studies), 2) knowledge synthesis (the aggregation of existing knowledge, e.g., systematic reviews), and 3) knowledge products and tools (knowledge presented in easy-to-understand formats, e.g., practice guidelines) (Menear et al., 2012). The action steps around the knowledge creation funnel facilitate moving knowledge into practice. Although depicted as a cycle, these actions may occur sequentially or simultaneously, and may be influenced by the knowledge stages (Strauss et al., 2011). It is vital that the end-users of the knowledge are included throughout the process to ensure their needs are being met.
